Why such a big difference  
between track and intensity?

Courtesy of Dr. G. Holland

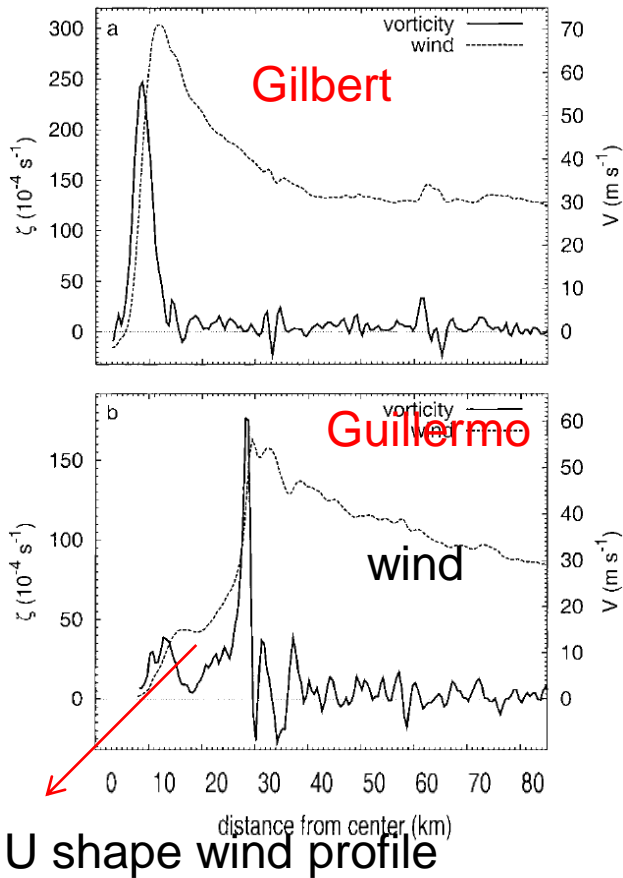

“Typhoon weakens over region of **cold water** or **low ocean heat content**, over land or region of decreased humidity, over region of **strong vertical wind shear**. 強垂直風切 冷海水 海水熱容小 颱風變弱

However, the variance of typhoon intensity change from climatology is **not** explained well by the synoptic-scale environmental conditions.

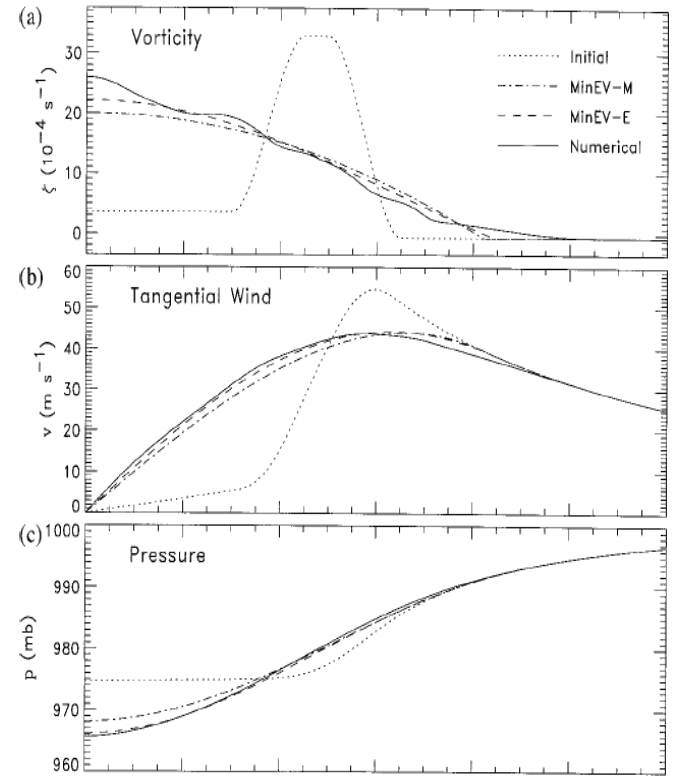

It is fairly typical for typhoons to strengthen or weakens **rapidly** without any clear commensurate changes in the environment.”

Rozoff et al. 2009

**Meso-scale processes matter!**

# Vertical Wind Shear and Convective Region in CE typhoons

Corbosiero and Molinari, 2003

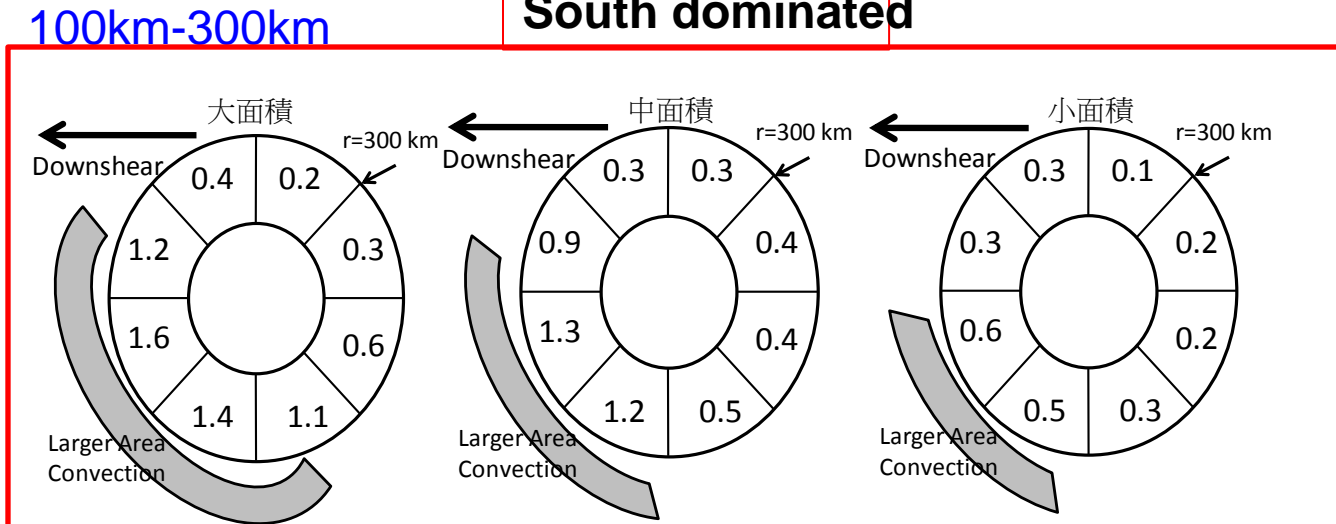

North dominated

100km-300km

South dominated

The outer region ( $r=100-300$ km) convections happen mostly in **down shear left**. Kuo 2011

## Importance of convections + the vorticity axisymmetrization dynamics.

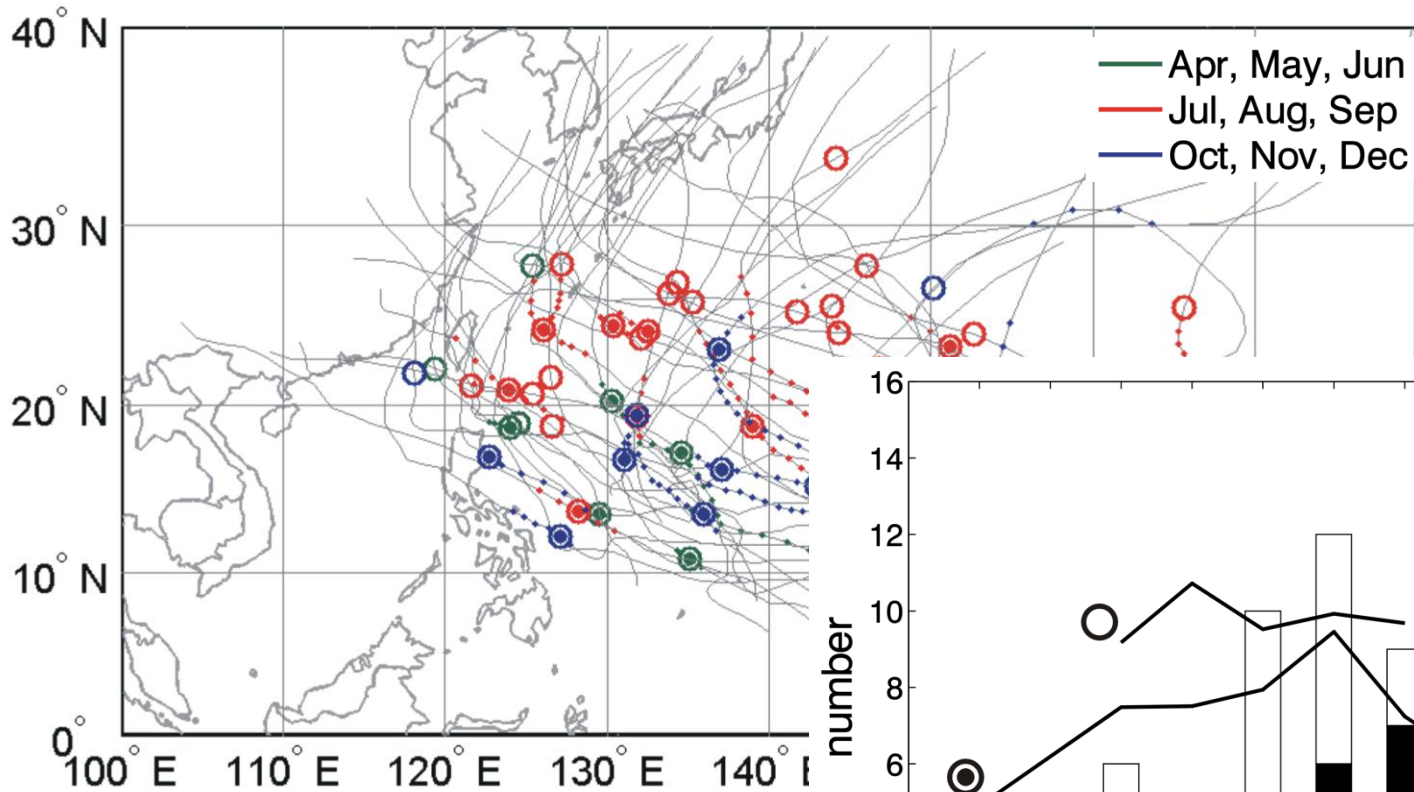

Kuo et al. (2004, 2008): Axisymmetrization of positive vorticity perturbations around a strong and tight core of vorticity.

Vertical Shear induced convection (the down-shear to the left convection) may also be a pathway to CE.

Vortex Rossby waves coupled to the boundary layer and convections may contribute to the **expansion of the tangential wind field**. *The unbalanced boundary layer response to an expanding swirling wind field is considered a very important mechanism for concentrating and sustaining deep convection in a narrow supergradient-wind zone in the outer-core vortex region.* (Huang et al. 2011)

Key feature of concentric eyewall formation appears to be the maintenance of a relative high intensity for a longer duration prior to formation, rather than a rapid intensification process that can reach a high intensity.

# Intensity change 24h before and after the formation of concentric eyewalls

**+**: intensity increase (P)

**-** : intensity decrease (N)

**+ -**

**--**

**++**

**- +**

It is possible that the large moat size may delay the eyewall replacement cycle and thus affect the TC intensity change.

The rapid filamentation process tends to make an important contribution to the organization of the moat size. Yang et al. 2011

# Summary

Importance of the vorticity axisymmetrization dynamics ( and the contraction of secondary wind maximum) + **convections**.

Double eyewall of different sizes maybe explained by the binary vortex interaction with skirted parameter.

The rapid filamentation process tends to make an important contribution to the organization of the moat size.

The barotropic idealization can yield insight into some of the organizational aspects of CE, it falls well short of vertical motion, the frictional boundary layer, and diabatic processes.

We found that the slow ERC cases are with larger moats, higher local SST and larger vertical shears 24 hours before CE formation.

This leads to a hypothesis that the larger vertical shear may contribute to a larger subsidence area, therefore a larger moat width. A larger moat width with a higher SST may cause the slow ERC.
